

Reaction rate and Reversible reaction.

Reaction rate

- The rate of a reaction is a measure of how quickly a reactant is used up, or a product is formed.
- Different chemical reactions occur at different rates. Some examples are illustrated in Table.

Type of reaction	Fast reaction	Slow reaction
Reaction involving liberation of a gas	Bubbles of carbon dioxide gas liberate rapidly when sodium carbonate powder reacts with dilute hydrochloric acid. $\text{Na}_2\text{CO}_3 (\text{s}) + 2\text{HCl}(\text{aq}) \rightarrow 2\text{NaCl}(\text{aq}) + \text{CO}_2 (\text{g}) + \text{H}_2\text{O}(\text{l})$	In photosynthesis, carbon dioxide reacts with water very slowly in the presence of sunlight and chlorophyll to produce glucose and oxygen gas. $6\text{CO}_2(\text{g}) + 6\text{H}_2\text{O}(\text{l}) \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 (\text{s}) + 6\text{O}_2 (\text{g})$
Precipitation reaction	When silver nitrate solution is added to sodium chloride solution, a white precipitate of silver chloride is formed immediately. $\text{AgNO}_3 (\text{aq}) + \text{NaCl}(\text{aq}) \rightarrow \text{AgCl}(\text{s}) + \text{NaNO}_3 (\text{aq})$	When dilute hydrochloric acid is added to sodium thiosulphate solution, a yellow precipitate of sulphur appears only after a few seconds. $\text{Na}_2\text{SO}_4 (\text{aq}) + 2\text{HCl}(\text{aq}) \rightarrow 2\text{NaCl}(\text{aq}) + \text{S}(\text{s}) + \text{SO}_2 (\text{g}) + \text{H}_2\text{O}(\text{l})$
Heating a metal in air	When a small piece of potassium is heated in air, it burns rapidly to form a white solid of potassium oxide. $4\text{K}(\text{s}) + \text{O}_2 (\text{g}) \rightarrow 2\text{K}_2\text{O}(\text{s})$	When a small piece of copper is heated in air, it reacts slowly with oxygen in the air to form a black solid of copper (II) oxide. $2\text{Cu}(\text{s}) + \text{O}_2 (\text{g}) \rightarrow 2\text{CuO}(\text{s})$

Measuring reaction rate

This is done by observing either the amount of reactants consumed or the amount of products formed per unit time. Some of the measurable visible changes in a chemical reaction are;

- Volume of gas liberated.
- Change in mass during a reaction.
- Colour changes.

Examples to illustrate how the rate of reaction is measured.

Reaction between magnesium and dilute sulphuric acid

- In the reaction between dilute sulphuric acid and a magnesium ribbon, the following two changes are observed:
 - The mass of magnesium (the reactant) decreases with time.
 - The volume of hydrogen gas (the product) increases with time.
- Hence, the rate of reaction between dilute sulphuric acid and magnesium can be determined by measuring the change in the mass of magnesium or the volume of hydrogen gas per unit time.

Collision theory and activation energy

- For particles to react, they have to collide with sufficient energy. (that means if they collide with less energy nothing happens)
- This sufficient energy is called **activation energy**.
- *The activation energy is the minimum amount of energy needed for a collision to be successful.*
- A collision that produces a reaction is called a **successful collision**.
- The greater the number of 'successful' collisions, the faster the rate of a reaction. This is called the '**collision theory**'.

The diagram below show activation energy for a reaction
